Norwegian Motor Claims Market: Trends and Opportunities for Autolyzer

Prepared by Ketevan Bachilava, data analyst intern at Autolyzer (Oslo), March 2026. This written version was reconstructed afterwards from my internship notes, using only data published by the end of March 2026. No confidential company data is included. Figures in brackets, e.g. [1], refer to the source list at the end.

1. Executive summary

Norway is one of the most favourable markets in the world for an AI-based damage assessment product, for four reasons:

- **Fewer claims, but each one costs more.** Motor insurers paid out almost NOK 24.1 billion in 2025, about the same as in 2024, even though claim frequency fell from 23.2% to 21.5% [1]. In the first half of 2025 the number of car claims dropped 6% while the average car claim rose 6% [2]. Insurers therefore compete on cost control per claim, which is exactly where repair-versus-replace decisions matter.
- **The fleet is becoming electric faster than anywhere else.** Battery-electric cars made up 95.9% of new passenger car registrations in 2025, and the electric fleet passed one million vehicles in early 2026 [6][5]. Electric cars are more complex and more expensive to repair, so the repair-or-replace decision is harder and the cost of a wrong call is higher.
- **Insurers are already automating claims.** Tryg announced in 2025 an AI model meant to handle most car claims without human involvement [9], and If already offers photo-based inspection where the workshop assesses customer photos [10]. The buyers understand the technology; the question is which supplier they trust.
- **Fraud and manipulated photos are a growing risk.** Motor vehicles accounted for 36% of detected non-life fraud cases in the first half of 2024, and exaggerated claims are typical in motor [7]. Fraudsters already reuse photos found online as evidence [8], and generative AI makes fake images even easier to produce.

Top opportunities for Autolyzer (details in section 6):

1. Triage at first notification of loss for insurers (repair vs replace plus cost estimate from photos).
2. Electric-vehicle specialisation (sensors, calibration, battery-related decisions).
3. A workshop-side tool and an accuracy-transparency dashboard for repair chains.
4. Image-authenticity and overstated-claim checks as an add-on module.

Main caution: the market is concentrated (a handful of insurers and a few workshop chains), global vendors such as Tractable and Solera already sell similar products, and parts of the data needed for a precise market size are not public. The sizing in section 5 is therefore an assumption-driven estimate, not a measured figure.

2. Market snapshot

Indicator	Value	Source
Motor insurance claims paid, 2025	NOK 24.1 billion (about the same as 2024)	[1]
Motor insurance claims paid, 2024	NOK 24.4 billion (+9.3% vs 2023)	[4]
Motor claim frequency, all vehicles	21.5% in 2025 (23.2% in 2024)	[1]
Claim frequency, cars and vans	29.7% in 2025 (31.7% in 2024)	[1]
Motor premium volume, Q2 2025	NOK 38.9 billion, +15.5% year on year	[3]
Average premium change, motor, 2024 to 2025	about +20.5% (industry association figure)	[4]
Registered passenger cars / light commercial vehicles	about 2.94 million / 519,000 (early 2026)	[5]
Electric share of new passenger cars, 2025	95.9% (88.9% in 2024)	[6]
Electric passenger cars in the fleet, early 2026	about 951,000, roughly one third of the fleet	[5]
Detected non-life insurance fraud, H1 2024	692 cases, NOK 88.4 million; motor 36% of cases	[7]

3. Key trends

3.1 Fewer accidents, more expensive repairs

Finans Norge describes 2025 as a year of fewer claims but high costs once an accident happens, with newer cars carrying more advanced technology and pricier components [1]. In the first half of 2025 claim numbers fell but payouts stayed flat because each claim cost more; collision liability claims rose almost 18% on average [2]. Glass damage was already a growing cost item in 2024 (NOK 1.2 billion in the first half, while the number of claims fell) [17].

Implication: the value of a better repair-or-replace decision grows with every increase in cost per claim, and averages hide big differences between damage types. This is why the alignment analysis by damage type (bumper, windshield, headlight and so on) is relevant for the business.

3.2 Electrification changes repair economics

Norway had about 951,000 electric passenger cars and 50,000 electric light commercial vehicles at the start of 2026, roughly a third of the passenger car fleet [5]. New registrations are almost entirely electric: 95.9% of new passenger cars in 2025, up from 88.9% in 2024 [6]. A consumer comparison site reports electric cars as roughly 30 to 35% more expensive to repair than combustion cars, with an

average electric-car repair around NOK 15,300 versus NOK 11,700 for petrol [12]. That site is a secondary source (an insurance comparison service), so these figures should be verified against Finans Norge or insurer data before use in sales material.

Implication: sensors in bumpers, camera and radar calibration, and battery-related damage push borderline cases toward replacement or even total loss. A model that is trained and validated specifically on electric models can differentiate itself.

3.3 Cost pressure and rising premiums

Premium volume for motor grew 15.5% year on year in Q2 2025, which Finans Norge links to more expensive cars and more expensive repairs [3]. Comparison sites point to a weak krone making imported parts more expensive and to sensor technology as the main drivers of premium increases in 2026 [12]. Insurers under public pressure about price have a strong incentive to prove they control claims costs.

3.4 Insurers are automating claims handling

- Tryg announced in March 2025 an AI model that should decide fault and process about 85% of its car claims without human staff, aiming for much faster handling [9]. Note that this concerns the fault decision rather than the damage estimate, so damage assessment remains a separate step.
- If's customer flow already sends a link by SMS so that the customer photographs the damage and the workshop assesses the pictures before booking a repair [10].
- A BCG analysis for the Nordic market estimates generative AI could reduce claims payouts by 3 to 4% and claims-handling costs by 20 to 30% [11].

Implication: photo-based assessment is accepted practice. Today the assessment is often done by a human at the workshop, which is the step an AI product can speed up and standardise.

3.5 Fraud, exaggeration and manipulated evidence

In the first half of 2024 Norwegian insurers detected 692 fraud cases in non-life insurance, worth NOK 88.4 million (up from 615 cases a year earlier). Motor vehicles accounted for 36% of these cases, and exaggerated claims, where a real damage is overstated, are more common in motor than in other products [7]. Fremtind has described customers submitting photos found online as evidence for their claims [8]; generative AI now makes such images far easier to fabricate.

Implication: an assessment tool that also checks whether photos are authentic and consistent with the claimed damage solves a second pain point and makes the product harder to replace.

3.6 Workshop consolidation

Independent body-repair chains are growing: Intakt Bilskade describes itself as Norway's largest independent chain, with about 21 workshops [13]; Werksta is part of a Nordic independent group, and Snap Drive reports 27 authorised workshops in the larger cities [13]. Cary Group has made several acquisitions in Norway [13]. The competition authority noted in a 2024 case that no market statistics exist for the repair market, and that the number of approved workshops is used as a proxy [16].

Implication: chains are a more efficient sales target than thousands of single workshops, and the absence of public market statistics means data-driven benchmarks (such as the Accuracy Gap dashboard) have real value.

3.7 Regulation

As of March 2026, the EU AI Act is not yet part of Norwegian law. The government sent a draft Norwegian AI Act for public consultation in June 2025, with entry into force expected around mid-2026, and the Norwegian Communications Authority (Nkom) has been designated as national supervisory authority [15]. GDPR already applies through the Personal Data Act, so the use of customer photos and claim data must follow Datatilsynet guidance. Systems whose output is used in the EU can already fall within the scope of the EU rules.

Implication: design for transparency now (keeping a human in the loop, logging recommendations and decisions). The Human-AI alignment dataset is exactly the evidence base regulators and customers will ask for.

4. Competitive landscape

Player type	Examples	Position	Gap for Autolyzer
Global AI estimators	Tractable, Solera Qapter	Photo-based damage detection and repair estimates for insurers and workshops; Qapter was rolled out to European body shops with a short pilot time [14]	Local Norwegian parts prices (NOK), local workshop labour rates, Norwegian language and processes, EV focus
Insurers building in-house	Tryg, If, Fremtind	Automating fault decisions and photo inspection [9][10]	Neutral third-party tool usable across insurers and workshops; benchmark data
Workshop chains	Intakt Bilskade, Werksta, Snap Drive, Cary Group	Customers, not competitors, but potential in-house tools	Estimation transparency; consistent pricing between sites
Insurance comparison and claim forms	Digital accident report services	Capture the form, not the damage assessment	Complement, possible integration partner

I did not find a Norwegian AI-damage-assessment start-up in my searches, but absence of evidence is not proof. A proper competitor matrix (pricing model, target segment, geography, AI capability, integrations), as suggested in the analysis ideas, should be built from direct research before any sales pitch.

5. Customers and market size

5.1 Customer segments

- **Insurers (priority 1).** The main groups are Gjensidige, If, Tryg, Fremtind, Storebrand and a tail of smaller companies. The only market-share figure I found is from Q4 2018 for the whole non-life market (Gjensidige 26%, If 21%, Fremtind 15%, Tryg including Troll and OBOS 13%, others 25%), so it is out of date and should be refreshed from Finans Norge statistics [18]. Claims handling is described as the moment of truth in the customer satisfaction survey EPSI Norge [19], so insurers care about speed and fairness.
- **Repair chains and workshops (priority 2).** Chains in section 3.6, plus independent workshops. A reliable count of workshops needs the Brønnøysund Register (NACE 45.20) and Proff.no, as planned in the analysis ideas; I could not verify a figure online, so the earlier range of 3,000 to 5,000 remains an unverified working estimate.
- **Fleets and leasing (priority 3).** About 519,000 light commercial vehicles are registered [5]; fleets benefit from fast, consistent damage checks but are fragmented.

5.2 Illustrative market sizing (assumption-driven)

Method: estimate yearly claims from the registered fleet and claim frequency, then apply an assumed fee per assessment. The fee levels and the share of assessable claims are my assumptions and must be replaced with Autolyzer pricing and real claim mix.

- Registered cars and light vans: about 2.94 million plus 0.52 million = 3.46 million [5]. Registered vehicles are used as a proxy for insured vehicles.
- Claim frequency for cars and vans: 29.7% [1]. Estimated claims per year: about 1.03 million (this includes all claim types, such as glass, theft and liability).
- Assumed share of claims suitable for photo assessment of own-vehicle damage: 40% (range 30 to 50%), giving about 410,000 claims.

Layer	Definition	Claims per year	Revenue at NOK 100 per claim	At NOK 250	At NOK 400
TAM	All motor claims	about 1.03 million	NOK 103 million	NOK 257 million	NOK 411 million
SAM	Photo-assessable damage claims (40%)	about 410,000	NOK 41 million	NOK 103 million	NOK 164 million
SOM	10% of SAM after about three years (assumption)	about 41,000	NOK 4.1 million	NOK 10.3 million	NOK 16.4 million

Cross-check from the value side: if AI reduced payouts by 3 to 4% as BCG estimates [11], the pool on NOK 24.1 billion of motor claims would be about NOK 0.72 to 0.96 billion per year. This is an upper bound on the value created for insurers, not revenue for Autolyzer, but it supports a value-based pricing discussion.

The point of this table is the order of magnitude: a realistic Norwegian market is in the tens of millions of NOK per year at a plausible fee, which means expansion to Sweden and Denmark, or higher-value modules such as fraud checks and benchmarking, will matter for the business case.

6. Opportunities (prioritised)

#	Opportunity	Evidence	How Autolyzer can win	Metric to track
1	First-notification triage for insurers: repair vs replace and a cost range from photos	Fewer but costlier claims [1][2]; photo inspection already in use [10]	Accuracy in NOK for Norwegian parts and labour; clear explanation to the human decision-maker	Accuracy rate within +/-10% of final invoice; alignment rate
2	Electric-vehicle specialisation	One million electric vehicles [5]; higher repair cost reported [12]	Models and price data tuned to the most common electric models in Norway	Override rate and accuracy on electric vs combustion cars
3	Workshop tool and transparency dashboard for chains	Consolidation [13]; no public repair market statistics [16]	Shop-level benchmark of estimate vs invoice; consistent estimates across sites	Accuracy gap by shop; share of shops with inflated invoices
4	Authenticity and overstated-claim checks	Motor is a major fraud category and exaggeration is typical [7]; photos reused from the web [8]	Add-on module reusing the same photo pipeline	Flag rate vs confirmed cases
5	Fleet and leasing inspection	519,000 light commercial vehicles [5]	Check-in and check-out damage comparison	Claims per fleet; time per inspection
6	Repair cost benchmark data product	Weak krone and rising parts costs [12]	Sell anonymised benchmarks to insurers and chains	Subscriptions; data coverage

7. Risks and threats

- **Concentrated buyers.** A few insurers decide most of the market; losing or failing to win one is a large share of the opportunity.
- **Global competition.** Tractable and Solera already have insurer relationships and large training datasets [14].
- **In-house development.** Tryg and others are building their own AI [9].

- **Trust and adoption.** If clients ignore recommendations, the product creates no value. This is exactly what the Human-AI alignment model measures.
- **Regulatory uncertainty.** Timing of the Norwegian AI Act is open, but transparency expectations are clear [15].
- **Data access.** Accuracy claims need final invoices from workshops; without those, quality cannot be proven.
- **Source quality.** Several market figures come from secondary sources (see limitations).

8. How this connects to the Human-AI alignment model

The workbook built for the internship measures how often clients follow the AI. The market findings suggest testable hypotheses:

1. **Electric cars should show higher override rates** because repair-or-replace choices are less obvious. Add a fuel-type column to the data to test this.
2. **Cases with a large price gap between replacement and repair** should show more overrides toward repair, supporting a price-sensitive suggestion engine (Price Gap sheet).
3. **Alignment should rise with AI confidence** (Confidence sheet). If it does not, the confidence score is not credible to users.
4. **Insurers and workshops may behave differently.** Add a customer-type column to compare them.
5. **Cost impact of overrides** (Cost Impact sheet) turns alignment into a business number that supports the sales argument.

9. Recommended next steps

1. Download the official Finans Norge claim datasets (quarterly and annual) and split by damage type and vehicle type, so that the fictive data can be calibrated.
2. Count workshops with Brønnøysund (NACE 45.20) and Proff.no and build the lead-scoring table, including chain membership.
3. Build the competitor matrix from direct research of Tractable, Solera Qapter, and any Nordic vendors.
4. Replace the assumed fee and assessable-share in section 5.2 with real pricing and the real claim mix, and rerun the sizing.
5. Load real company data into the alignment workbook and test the five hypotheses above.
6. Add fuel type and customer type to the data schema now, so future analysis is possible.

10. Limitations

- Market size in section 5.2 is illustrative and depends on assumptions flagged in the text.
- Insurer market shares are from 2018 and outdated.
- Electric-car repair-cost figures come from a comparison website, not from official statistics.
- Information about Tryg's AI model comes from a consultancy article about an announcement; actual results may differ.
- I could not find a verified count of Norwegian repair shops.

- Figures from different years and sources are not always comparable (for example claims paid versus premium volume).
